

## General Description

The ICS874001I-02 is a high performance Jitter Attenuator designed for use in PCI Express™ systems. In some PCI Express systems, such as those found in desktop PCs, the PCI Express clocks are generated from a low bandwidth, high phase noise PLL frequency synthesizer. In these systems, a jitter attenuator may be required to attenuate high frequency random and deterministic jitter components from the PLL synthesizer and from the system board. The ICS874001I-02 has two different PLL bandwidth modes: 2MHz and 3MHz. The 2MHz mode will provide maximum jitter attenuation, but with higher PLL tracking skew and spread spectrum modulation from the motherboard synthesizer may be attenuated. The 3MHz bandwidth provides the best tracking skew and will pass most spread profiles, but the jitter attenuation will not be as good as the lower bandwidth mode. The 874001I-02 can be set for different modes using the F\_SELx pins, as shown in Table 3C.

The ICS874001I-02 uses IDT's 3<sup>RD</sup> Generation FemtoClock® PLL technology to achieve the lowest possible phase noise. The device is packaged in a small 20-pin TSSOP package, making it ideal for use in space constrained applications such as PCI Express add-in cards.

## Features

- One differential LVDS output pair
- One differential clock input
- CLK, nCLK can accept the following differential input levels: LVPECL, LVDS, LVHSTL, HCSL, SSTL
- Input frequency range: 98MHz to 128MHz
- Output frequency range: 98MHz to 640MHz
- VCO range: 490MHz - 640MHz
- Cycle-to-cycle jitter: 15ps (maximum), 3.3V
- RMS period jitter: 3ps (maximum), 3.3V
- Two bandwidth modes allow the system designer to make jitter attenuation/tracking skew design trade-offs
- Full 3.3V or 2.5V operating supply
- -40°C to 85°C ambient operating temperature
- Available in lead-free (RoHS 6) package

## Block Diagram

**Table 1. Pin Descriptions**

Number	Name	Type		Description
1	PLL_SEL	Input	Pullup	PLL select pin. When LOW, bypasses the VCO. When HIGH selects VCO. LVCMOS/LVTTL interface levels.
2, 3, 4, 15, 16, 20	nc	Unused		No connect.
5	MR	Input	Pulldown	Active High Master Reset. When logic HIGH, the internal dividers are reset causing the true output Q to go LOW and the inverted output nQ to go HIGH. When logic LOW, the internal dividers and the outputs are enabled. LVCMOS/LVTTL interface levels.
6	BW_SEL	Input	Pulldown	PLL Bandwidth select pin. LVCMOS/LVTTL interface levels. See Table 3B.
7	F_SEL1	Input	Pullup	Frequency select pin. See Table 3C. LVCMOS/LVTTL interface levels.
8	V <sub>DDA</sub>	Power		Analog supply pin.
9	F_SEL0	Input	Pulldown	Frequency select pin. See Table 3C. LVCMOS/LVTTL interface levels.
10	V <sub>DD</sub>	Power		Core supply pin.
11	OE	Input	Pullup	Output enable. When HIGH, outputs are enabled. When LOW, forces outputs to High-Impedance state. LVCMOS/LVTTL interface levels. See Table 3A.
12	CLK	Input	Pulldown	Non-inverting differential clock input.
13	nCLK	Input	Pullup	Inverting differential clock input.
14	GND	Power		Power supply ground.
17, 18	nQ, Q	Output		Differential output pair. LVDS interface levels.
19	V <sub>DDO</sub>	Power		Output supply pin.

NOTE: *Pullup* and *Pulldown* refer to internal input resistors. See Table 2, *Pin Characteristics*, for typical values.

## Absolute Maximum Ratings

NOTE: Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only. Functional operation of product at these conditions or any conditions beyond those listed in the *DC Characteristics* or *AC Characteristics* is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

Item	Rating
Supply Voltage, $V_{DD}$	4.6V
Inputs, $V_I$	-0.5V to $V_{DD} + 0.5V$
Outputs, $I_O$ Continuous Current Surge Current	10mA 15mA
Package Thermal Impedance, $\theta_{JA}$	86.7°C/W (0 mps)
Storage Temperature, $T_{STG}$	-65°C to 150°C

### Power Supply Filtering Technique

As in any high speed analog circuitry, the power supply pins are vulnerable to random noise. To achieve optimum jitter performance, power supply isolation is required. The ICS874001I-02 provides separate power supplies to isolate any high switching noise from the outputs to the internal PLL.  $V_{DD}$ ,  $V_{DDA}$  and  $V_{DDO}$  should be individually connected to the power supply plane through vias, and  $0.01\mu\text{F}$  bypass capacitors should be used for each pin. *Figure 1* illustrates this for a generic  $V_{DD}$  pin and also shows that  $V_{DDA}$  requires that an additional  $10\Omega$  resistor along with a  $10\mu\text{F}$  bypass capacitor be connected to the  $V_{DDA}$  pin.

Figure 1. Power Supply Filtering

### Wiring the Differential Input to Accept Single-Ended Levels

*Figure 2* shows how a differential input can be wired to accept single ended levels. The reference voltage  $V_{REF} = V_{DD}/2$  is generated by the bias resistors  $R1$  and  $R2$ . The bypass capacitor ( $C1$ ) is used to help filter noise on the DC bias. This bias circuit should be located as close to the input pin as possible. The ratio of  $R1$  and  $R2$  might need to be adjusted to position the  $V_{REF}$  in the center of the input voltage swing. For example, if the input clock swing is  $2.5\text{V}$  and  $V_{DD} = 3.3\text{V}$ ,  $R1$  and  $R2$  value should be adjusted to set  $V_{REF}$  at  $1.25\text{V}$ . The values below are for when both the single ended swing and  $V_{DD}$  are at the same voltage. This configuration requires that the sum of the output impedance of the driver ( $R_o$ ) and the series resistance ( $R_s$ ) equals the transmission line impedance. In addition, matched termination at the input will attenuate the signal in half. This can be done in one of two ways. First,  $R3$  and  $R4$  in parallel should equal the transmission

line impedance. For most  $50\Omega$  applications,  $R3$  and  $R4$  can be  $100\Omega$ . The values of the resistors can be increased to reduce the loading for slower and weaker LVCMOS driver. When using single-ended signaling, the noise rejection benefits of differential signaling are reduced. Even though the differential input can handle full rail LVCMOS signaling, it is recommended that the amplitude be reduced. The datasheet specifies a lower differential amplitude, however this only applies to differential signals. For single-ended applications, the swing can be larger, however  $V_{IL}$  cannot be less than  $-0.3\text{V}$  and  $V_{IH}$  cannot be more than  $V_{DD} + 0.3\text{V}$ . Though some of the recommended components might not be used, the pads should be placed in the layout. They can be utilized for debugging purposes. The datasheet specifications are characterized and guaranteed by using a differential signal.

Figure 2. Recommended Schematic for Wiring a Differential Input to Accept Single-ended Levels

## Differential Clock Input Interface

The CLK /nCLK accepts LVDS, LVPECL, LVHSTL, SSTL, HCSL and other differential signals. Both signals must meet the  $V_{PP}$  and  $V_{CMR}$  input requirements. *Figures 3A to 3F* show interface examples for the CLK/nCLK input driven by the most common driver types. The input interfaces suggested here are examples only. Please consult with the

vendor of the driver component to confirm the driver termination requirements. For example, in Figure 3A, the input termination applies for IDT open emitter LVHSTL drivers. If you are using an LVHSTL driver from another vendor, use their termination recommendation.

**3A. CLK/nCLK Input Driven by an IDT Open Emitter LVHSTL Driver**

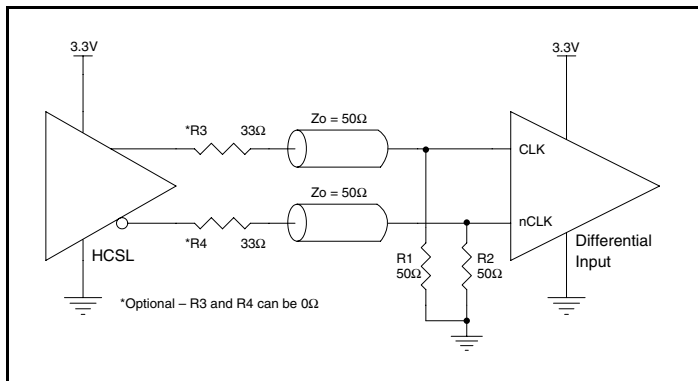

**Figure 3B. CLK/nCLK Input Driven by a 3.3V LVPECL Driver**

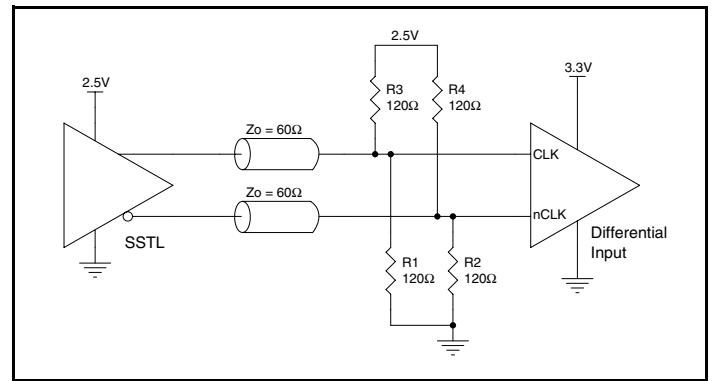

**Figure 3C. CLK/nCLK Input Driven by a 3.3V LVPECL Driver**

**Figure 3D. CLK/nCLK Input Driven by a 3.3V LVDS Driver**

**Figure 3E. CLK/nCLK Input Driven by a 3.3V HCSL Driver**

**Figure 3F. CLK/nCLK Input Driven by a 2.5V SSTL Driver**

## Recommendations for Unused Input Pins

### Inputs:

#### LVC MOS Control Pins

All control pins have internal pull-ups or pull-downs; additional resistance is not required but can be added for additional protection. A 1k $\Omega$  resistor can be used.

### LVDS Driver Termination

A general LVDS interface is shown in *Figure 4*. Standard termination for LVDS type output structure requires both a 100 $\Omega$  parallel resistor at the receiver and a 100 $\Omega$  differential transmission line environment. In order to avoid any transmission line reflection issues, the 100 $\Omega$  resistor must be placed as close to the receiver as possible. IDT offers a full line of LVDS compliant devices with two types of output structures: current source and voltage source. The standard

termination schematic as shown in *Figure 4* can be used with either type of output structure. If using a non-standard termination, it is recommended to contact IDT and confirm if the output is a current source or a voltage source type structure. In addition, since these outputs are LVDS compatible, the amplitude and common mode input range of the input receivers should be verified for compatibility with the output.

**Figure 4. Typical LVDS Driver Termination**

## Schematic Layout

Figure 5 shows an example of ICS874001I-02 application schematic. In this example, the device is operated at  $V_{DD} = 3.3V$ . The decoupling capacitors should be located as close as

possible to the power pin. The input is driven by a 3.3V LVPECL driver.

Figure 5. ICS874001I-02 Schematic Layout

## Power Considerations

This section provides information on power dissipation and junction temperature for the ICS874001I-02. Equations and example calculations are also provided.

### 1. Power Dissipation.

The total power dissipation for the ICS874001I-02 is the sum of the core power plus the analog power plus the power dissipated in the load(s). The following is the power dissipation for  $V_{DD} = 3.3V + 5\% = 3.465V$ , which gives worst case results.

- Power (core)<sub>MAX</sub> =  $V_{DD\_MAX} * (I_{DD\_MAX} + I_{DDA\_MAX}) = 3.465V * (72mA + 12mA) = \mathbf{291.06mW}$
- Power (outputs)<sub>MAX</sub> =  $V_{DDO\_MAX} * I_{DDO\_MAX} = 3.465V * 24mA = \mathbf{83.16mW}$

**Total Power<sub>MAX</sub> = 291.06mW + 83.16mW = 374.22mW**

•

### 2. Junction Temperature.

Junction temperature,  $T_j$ , is the temperature at the junction of the bond wire and bond pad directly affects the reliability of the device. The maximum recommended junction temperature is 125°C. Limiting the internal transistor junction temperature,  $T_j$ , to 125°C ensures that the bond wire and bond pad temperature remains below 125°C.

The equation for  $T_j$  is as follows:  $T_j = \theta_{JA} * Pd\_total + T_A$

$T_j$  = Junction Temperature

$\theta_{JA}$  = Junction-to-Ambient Thermal Resistance

$Pd\_total$  = Total Device Power Dissipation (example calculation is in section 1 above)

$T_A$  = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance  $\theta_{JA}$  must be used. Assuming no air flow and a multi-layer board, the appropriate value is 86.7°C/W per Table 6 below.

Therefore,  $T_j$  for an ambient temperature of 85°C with all outputs switching is:

$$85^\circ\text{C} + 0.374\text{W} * 86.7^\circ\text{C/W} = 117^\circ\text{C}. \text{ This is below the limit of } 125^\circ\text{C}.$$

This calculation is only an example.  $T_j$  will obviously vary depending on the number of loaded outputs, supply voltage, air flow and the type of board (multi-layer).

**Table 6. Thermal Resistance  $\theta_{JA}$  for 20 Lead TSSOP, Forced Convection**

Meters per Second	$\theta_{JA}$ by Velocity		
	0	1	2.5
Multi-Layer PCB, JEDEC Standard Test Boards	86.7°C/W	82.4°C/W	80.2°C/W

## Reliability Information
