

40MHz to 3.8GHz RF Power Detector with 75dB Dynamic Range

FEATURES

- Frequency Range: 40MHz to 3.8GHz
- 75dB Log Linear Dynamic Range
- Exceptional Accuracy over Temperature
- Linear DC Output vs. Input Power in dBm
- -72dBm Detection Sensitivity
- Single-ended RF Input
- Low Supply Current: 29mA
- Supply Voltage: 3V to 5.25V
- 8-lead DFN 3mm × 3mm package

APPLICATIONS

- Received Signal Strength Indication (RSSI)
- RF Power Measurement and Control
- RF/IF Power Detection
- Receiver RF/IF Gain Control
- Envelope Detection
- ASK Receiver

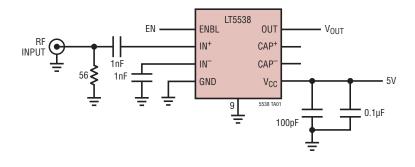

DESCRIPTION

The LT®5538 is a 40MHz to 3800MHz monolithic logarithmic RF power detector, capable of measuring RF signals over a wide dynamic range, from –75dBm to 10dBm. The RF signal in an equivalent decibel-scaled value is precisely converted into DC voltage on a linear scale. The wide linear dynamic range is achieved by measuring the RF signal using cascaded RF limiters and RF detectors. Their outputs are summed to generate an accurate linear DC voltage proportional to the input RF signal in dBm. The LT5538 delivers superior temperature stable output (within ±1dB over full temperature range) from 40MHz to 3.8GHz. The output is buffered with a low impedance driver.

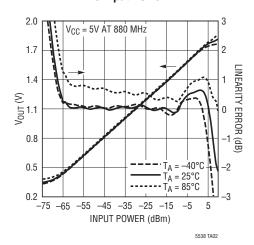

CT, LT, LTC and LTM are registered trademarks of Linear Technology Corporation.

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: Specifications over the -40° C to 85°C temperature range are assured by design, characterization and correlation with statistical process control.

Note 3: The linearity error is calculated by the difference between the incremental slope of the output and the average slope from -50dBm

to $-20 \mbox{dBm}$. The dynamic range is defined as the range over which the linearity error is within $\pm 1 \mbox{dB}$.

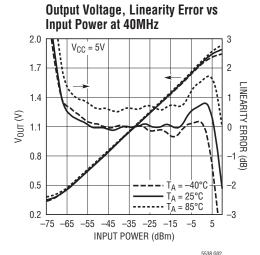

Note 4: Sensitivity is defined as the minimum input power required for the linearity error within 3dB of the ideal log-linear transfer curve.

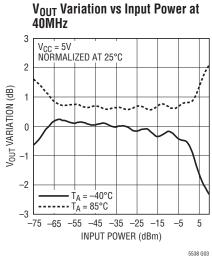

Note 5: Logarithmic Intercept is an extrapolated input power level from the best-fitted log-linear straight line, where the output voltage is OV.

PIN FUNCTIONS

ENBL (Pin 1): Enable Pin. An applied voltage above 1V will activate the bias for the IC. For an applied voltage below 0.3V, the circuits will be shut down (disabled) with a corresponding reduction in power supply current. If the enable function is not required, then this pin can be connected to V_{CC} . Typical enable pin input currents are $100\mu A$ for EN = 3V and $200\mu A$ for EN = 5V, respectively. Note that at no time should the ENBL pin voltage be allowed to exceed V_{CC} by more than 0.3V.

IN⁺ (**Pin 2**): RF Input Pin. The pin is internally biased to V_{CC} –0.5V and should be DC blocked externally. The input is connected via internal 394 Ω resistor to the IN⁻ pin which should be connected to ground with an ac-decoupling capacitor.

IN⁻ (**Pin 3**): AC Ground Pin. The pin is internally biased to V_{CC} –0.5V and coupled to ground via internal 20pF capacitor.

This pin should be connected to ground with an external ac-decoupling capacitor for low frequency operation.

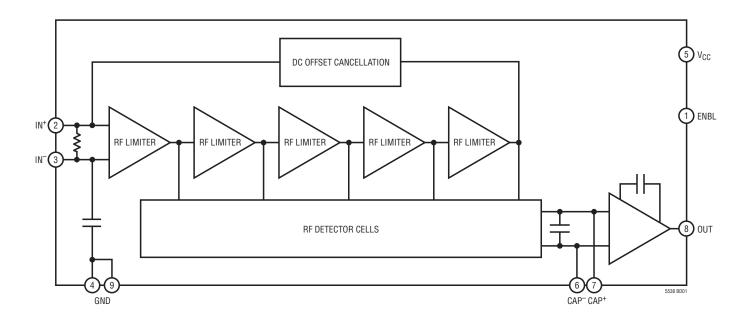

GND (Pin 4, Exposed Pad Pin 9): Circuit Ground Return for the entire IC. This pin must be soldered to the printed circuit board ground plane.

 V_{CC} (Pin 5): Power Supply Pin. This pin should be decoupled using 100pF and $0.1\mu F$ capacitors.

CAP⁻, **CAP**⁺ (**Pins 6**, **7**): Optional Filter Capacitor Pins. These pins are internally connected to the detector outputs in front of the output buffer amplifier. An external low-pass filtering can be formed by connecting a capacitor to Vcc from each pin for filtering a low frequency modulation signal. See the Applications Information section for detail.

OUT (Pin 8): Detector DC Output Pin.

BLOCK DIAGRAM

APPLICATIONS INFORMATION

The LT5538 is a 40MHz to 3.8 GHz logarithmic RF power detector. It consists of cascaded limiting amplifiers and RF detectors. The output currents from every RF detector are combined and low-pass filtered before applied to the output buffer amplifier. As a result, the final DC output voltage approximates the logarithm of the amplitude of the input signal. The LT5538 is able to accurately measure an RF signal over a 70dB dynamic range (-68dBm to 2dBm at 2.1GHz) with 50Ω single-ended input impedance. The slope of linear to log transfer function is about 17.7mV/dB at 2.1GHz. Within the linear dynamic range, very stable output is achieved over the full temperature range from -40°C to 85°C and over the full operating frequency range from 40MHz to 3.8GHz. The absolute variation over temperature is typically within ±1dB over 65dB dynamic range at 2.1GHz.

RF INPUT

The simplified schematic of the input circuit is shown in Figure 1. The IN+ and IN- pins are internally biased to V_{CC} –0.5V. The IN- pin is internally coupled to ground via 20pF capacitor. An external capacitor of 1nF is needed to connect this pin to ground for low frequency operation. The impedance between IN+ and IN- is about 394 Ω . The RF input pin IN+ should be DC blocked when connected to ground or other matching components. A 56Ω resistor (R1) connected to ground will provide better than 10dB input return loss over the operating frequency range up to 1.5GHz. At higher operating frequency, additional LC

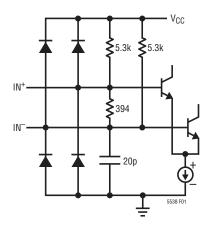

Figure 1. Simplified Schematic of the Input Circuit

matching elements are needed for a proper impedance matching to a 50Ω source as shown in Figure 2. Refer to Figure 6 for the circuit schematic of the input matching network. The input impedance vs frequency of the RF input port IN⁺ is detailed in Table 1.

APPLICATIONS INFORMATION

OUTPUT INTERFACE

The output interface of the LT5538 is shown in Figure 3. This output buffer circuit can source 10mA current to the load and sink 200 μ A current from the load. The small-signal output bandwidth is approximately 4MHz when the output is resistively terminated or open. The full-scaled 10% to 90% rise and fall times are 100nS and 180nS, respectively. The output transient responses at varied input power levels are shown in Figure 4.

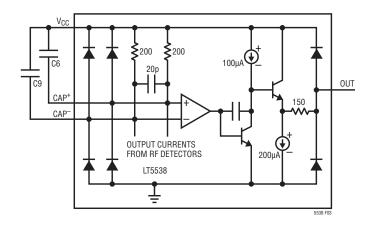

Figure 3. Simplified Schematic of the Output Interface

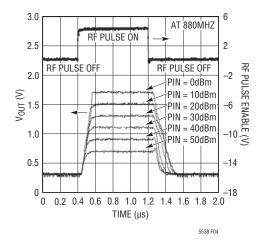

Figure 4. Simplified Circuit Schematic of the Output Interface

When the part is enabled, the output impedance is about 150Ω . When it is disabled, the output impedance is about $29.5k\Omega$ referenced to ground.

EXTERNAL FILTERING AT CAP+, CAP-

The CAP⁺ and CAP⁻ Pins are internally biased at V_{CC} –0.36V via a 200 Ω resistor from voltage supply V_{CC} as shown in Figure 3. These two pins are connected to the differential outputs of the internal RF detector cells. In combination with the 20pF in parallel, a low-pass filter is formed with -3dB corner frequency of 20MHz. The high frequency rectified signals (particularly second-order harmonic of the RF signal) from the detector cells are filtered and then the DC output is amplified by the output buffer amplifier. In some applications, the LT5538 may be used to measure a modulated RF signal with low frequency AM content (lower than 20MHz), a large modulation signal may be present at these two pins due to insufficient low-pass filtering, resulting in output voltage fluctuation at the LT5538's output. Its DC content may also vary depending upon the modulation frequency. To assure stable DC output of the LT5538, external capacitors C6 and C9 can be connected from CAP⁺ and CAP⁻ to V_{CC} to filter out this low frequency AM modulation signal. Assume the modulation frequency of the RF signal is f_{MOD}, the capacitor value in Farads of C6 and C9 can be chosen by the following formula:

C6 (or C9)
$$\geq 10/(2\pi \cdot 200 \cdot f_{MOD})$$

Do not connect these two filtering capacitors to ground or any other low voltage reference at any time to avoid an abnormal start-up condition.

APPLICATIONS INFORMATION

ENBL (ENABLE) PIN OPERATION

A simplified circuit schematic of the ENBL Pin is shown in Figure 5. The enable voltage necessary to turn on the LT5538 is 1V. The current drawn by the ENBL pin varies with the voltage applied at the pin. When the ENBL voltage is 3V, the ENBL current is typically 100 μ A. When the ENBL voltage is 5V, the ENBL current is increased to 200

 μA . To disable or turn off the chip, this voltage should be below 0.3V. It is important that the voltage applied to the ENBL pin should never exceed V_{CC} by more than 0.3V. Otherwise, the supply current may be sourced through the upper ESD protection diode connected at the ENBL pin. Under no circumstances should voltage be applied to the ENBL Pin before the supply voltage is applied to the V_{CC} pin. If this occurs, damage to the IC may result.
